Understanding Dasgupta's Clustering Cost and Objectives

What is Dasgupta's Clustering Cost?

Dasgupta's clustering cost is a metric designed to evaluate the quality of hierarchical clustering algorithms. It measures how well a tree structure reflects the inherent similarities within the data. Formally, given a weighted similarity graph $G = (V, E, w)$, where V is the set of data points, each edge weight $w(u, v)$ indicates the similarity between points u and v , the clustering cost for a hierarchical tree T is calculated as:

$$\text{Cost}(T) = \sum_{(u, v) \in E} w(u, v) \times |\text{LCA}_T(u, v)|$$

where $|\text{LCA}_T(u, v)|$ is the height of the least common ancestor of u and v in the tree T . The goal is to find a tree T that minimizes this cost, effectively grouping similar points closer together.

Objectives of Dasgupta's Solutions

The primary objectives involve:

- Developing algorithms that approximate the minimal clustering cost efficiently.

- Providing theoretical guarantees on the quality of solutions relative to the optimal.
- Designing algorithms that are scalable to large datasets.

- **Solution Steps:**
 - Define variables representing cluster assignments or hierarchy levels.
 - Set up the objective function corresponding to Dasgupta's cost.
 - Relax integer or combinatorial constraints to continuous ones.
 - Solve the relaxation efficiently using existing solvers.
 - Round the fractional solution to obtain a hierarchical clustering.

Core Concepts in Dasgupta's Algorithms

Hierarchical Clustering and Cost Functions

At the heart of Dasgupta's work is the concept of hierarchical clustering, which involves creating a tree-like structure that groups similar elements together at various levels.

Dasgupta's cost function for hierarchical clustering is designed to quantify the quality of a clustering tree. Given a similarity graph, the goal is to build a tree that minimizes the total clustering cost.

Formal Definition of the Cost Function

Suppose you have a weighted similarity graph $G = (V, E)$ with weights w_{ij} for edges between vertices i and j . The Dasgupta cost of a hierarchical clustering tree T over V is:

$$\text{Cost}(T) = \sum_{(i,j) \in E} w_{ij} \cdot |\text{LCA}_T(i,j)|$$

$$\text{Cost}(T) = \sum_{(i,j) \in E} w_{ij} \cdot |\text{LCA}_T(i,j)|$$

$$\text{Cost}(T) = \sum_{(i,j) \in E} w_{ij} \cdot |\text{LCA}_T(i,j)|$$

where:

- $|\text{LCA}_T(i,j)|$ is the label (or cluster size) of the lowest common ancestor of i and j in the tree T .

The intuition: edges connecting similar elements should be merged early (at lower levels), minimizing the contribution of long-distance or high-level merges to the total cost.

Approaches and Algorithms for Solutions
